FOREWORD

This study was initiated by the Anthropology Branch, Human Engineering Division, Behavioral Sciences Laboratory, 6570th Aerospace Medical Research Laboratories. The research was conducted by North American Aviation, Inc., Los Angeles 9, California, under the provisions of Contract No. AF 33(657)-7848. Mr. William R. Santschi, Head of the Bioscience Unit, Life Sciences Group, was the principal investigator for North American Aviation, Inc. Mr. J. DuBois, Biophysicist, was responsible for the theoretical aspects of the study. Selection of subjects and anthropometry phases of the study were conducted by Miss Constance Omoto, Physical Anthropologist. Mr. Charles E. Clauser, of the Anthropology Branch, monitored the contract for the 6570th Aerospace Medical Research Laboratories. The work was performed in support of Project No. 7184, "Human Performance in Advanced Systems," Task No. 718408, "Anthropology for Design." The research sponsored by this contract was initiated in February 1962 and completed in August 1962. This report is cataloged by North American Aviation as NA-62-250.

The authors wish to express appreciation to Mr. H. T. E. Hertzberg, Chief of the Anthropology Branch, for a critical review of the manuscript. Gratitude is also expressed to staff members, Mr. M. N. Goldberg, Mr. D. Walton, and Mr. A. P. Holm, for their assistance in measuring the subjects, and to Mr. F. Mazy, Senior Design Specialist, for the design of the measurement apparatus. The authors are particularly indebted to the NAA-employee subjects whose cooperation in voluntarily submitting to the rigors of measurement made this study possible.

ABSTRACT

A study was conducted to determine the moments of inertia and centers of gravity of a sample of 66 living male subjects representative of the Air Force population in stature and weight. Eight body positions were investigated: Standing; Standing, Arms Over Head; Spread Eagle; Sitting; Sitting, Forearms Down; Sitting, Thighs Elevated; Mercury Configuration; Relaxed (Weightless). The procedure was based upon the compound pendulum having a theoretical accuracy of approximately ± 2 to ± 8 per cent depending upon position and axis. Orthogonal axes, defined as the intersections of the sagittal, frontal, and transverse planes through the standing body, were designated as X, Y, and Z. A set of 50 anthropometric dimensions was taken on each subject, as well as photographs of each subject in each position. Results of the study show that the average moment of inertia varied in this sample from 11 lb. in sec.² about the Z axis to 152 lb. in sec.² about the X axis. Linear regression analysis of moments of inertia vs. stature and weight yielded correlation coefficients ranging between 0.77 and 0.98.

MOMENTS OF INERTIA AND CENTERS OF GRAVITY
OF THE
LIVING HUMAN BODY

INTRODUCTION

Moments of inertia and centers of gravity of the human body are fundamental parameters which enter into all computations involving body rotation. These computations arise in the analysis of total body motion under conditions of weightlessness, where body rotation of an individual is easily produced by his own action or by external forces; under conditions of acceleration, where the vector does not act through the body center of gravity due to body position or restraint; and, in general, in the design of air or space transport systems where human weight is a significant percentage of vehicle weight.

The purpose of this study is twofold; first, to obtain data on the characteristics of the moment-of-inertia parameter about three axes and for various body positions for a well-defined group of living humans; and, second, to supplement the existing data on the location of the center of gravity of the total human body.

Earlier investigators have used pendulum techniques to obtain data on human body segment moments of inertia and centers of gravity for a small number of cadaver subjects (references 2, 3). In the measurement of living humans, balance techniques have been employed to obtain total body center of gravity (references 8, 10). One investigator has utilized volume contour maps to measure total body center of gravity and moment of inertia, a method which involved assumptions about body cross section and density (reference 11).

The present study makes use of a generalized compound pendulum method in which the only assumption made is mean body density, utilized in computing a small second-order buoyancy correction factor.

SECTION I

THEORETICAL CONSIDERATIONS

METHOD

The technical aspects of the compound pendulum method, upon which this study is based, are treated in detail in reference 4; a brief description is presented here for general background.

The compound or physical pendulum is an elementary dynamic system consisting of an extended mass oscillating about a fixed horizontal axis under the force of gravity. If two parallel axes of oscillation are provided, and certain simplifying assumptions made, it is not difficult to show that the simultaneous solution of the torque equations for the two axes yields expressions for the moment of inertia and center of gravity of the pendulum in terms of its weight, periods, axis separation and acceleration due to gravity. Since the sums of the moments of inertia of two or more masses with respect to the same axis equals the moment of inertia of the combined masses with respect to that axis, the moment of inertia and center of gravity of a mass (the human subject) distinct from the double axis pendulum can be found.

In reference 4 it is shown that the distance from the short suspension axis (figure 1) to the center of gravity of the subject is given by

$$L_s = \frac{\frac{4\pi^2}{g} \Delta L \left[\left(\frac{W'}{g} + \rho V' \right) (2L'_s + \Delta L) + \Delta L \left(\frac{W}{g} + \rho V \right) - \frac{T_{pl}^2}{4\pi^2} (W + V') \right] - W' L'_s (T_{pl}^2 - T_{ps}^2)}{W(T_{pl}^2 - T_{ps}^2) - 8\pi^2 \left(\frac{W'}{g} + \rho V \right) \Delta L},$$

while the moment of inertia of the subject about an axis parallel to the fulcrum axis and passing through his center of gravity is given by

$$I_o = \frac{T_{ps}^2}{4\pi^2} (W' L'_s + WL_s) - I'_s - \left(\frac{W}{g} + \rho V \right) L_s^2.$$

Where:

T_{ps} is the period of the pendulum about the short suspension axis

T_{pl} is the period of the pendulum about the long suspension axis

I'_s is the moment of inertia of the pendulum (without subject) about the short axis

- A - Long suspension axis
- B - Short suspension axis
- θ - Angular displacement of pendulum
- W' - Weight of pendulum without subject
- W - Weight of subject
- ΔL - Distance between support axes
- L_s' - Distance from short suspension axis to CG of pendulum
- L_1' - Distance from long suspension axis to CG of pendulum
- L_s - Distance from short suspension axis to CG of subject
- L_1 - Distance from long suspension axis to CG of subject

Figure 1. Schematic of Compound Pendulum

g is the acceleration due to gravity

V is the subject volume based upon body weight and an assumed mean body density of 65.246 lb/ft^3

V' is the pendulum volume

ρ is the ambient air density

The remaining symbols are as given previously.

A given determination of center of gravity and moment of inertia involves only five measurements: air temperature, subject weight, the two pendulum periods about the short and long suspension axes and a reference distance from the subject to the short suspension fulcrum. All other constants in the equations are determined, once, prior to the actual subject measurements.

Also noteworthy is the fact that the center of gravity measurement is made in proper relationship with the gravity vector as contrasted with other methods (references 8 and 10) in which the displacement of subcutaneous fat and viscera is orthogonal to the direction of measurement.

ACCURACY

The theoretical limits of accuracy obtainable with the compound pendulum technique (as applied to living human measurement) was estimated (reference 4) from the total differentials of I_{cg} and I_o . These limits depend upon the magnitude of the moment of inertia which in turn is a function of body weight, anthropometry, body position and axis. Provided the crucial experimental variables are carefully controlled, accuracies of $\pm 2\%$ for maximum I_o values and $\pm 8\%$ for minimum I_o values appear within the realm of possibility (reference 4). The distance to the center of gravity can be measured to within $\pm 0.5\%$ or better along the X and Z axes.

Some of the practical considerations in achieving these estimated limits are touched upon in Section III.

DATA RECORDING AND PROCESSING

Since an enormous quantity of raw data is generated rapidly when a large number of subjects are measured for moment of inertia and cg in eight distinct positions about three body axes, a 7090 computer program was written to calculate individual I_o and I_{cg} values and to carry out the statistical analysis on the computed moments and cgs. Perhaps unique in this study is the total integration of the experimental procedure with the data processing. This was achieved by recording all data, anthropometry included, directly on decimal data key punch sheets, an arrangement designed to minimize transcription errors and provide an orderly procedure for the experiment.

The computer program was written in Fortran and consists of a main program and five subroutines. Three of the latter are used where required to compute averages, standard deviations, simple and multiple regression correlation coefficients, equation constants and standard errors of estimates. All of the printout data tables in this report were generated by the other two subroutines.

BODY COORDINATE SYSTEM

An orthogonal axis system was defined by the intersection of the three principal planes of the body passing through the center of gravity of the body as shown in figure 2. The Z-axis is formed by the intersection of the sagittal plane and the frontal plane; the Y-axis, by the intersection of the frontal and transverse planes; and, the X-axis, by the intersection of the sagittal and transverse planes.

Figure 2. Body Coordinate System

The orthogonal axis system was referenced to the body as shown in figure 3. The location of the center of gravity of the body was measured along the Z-axis from the top of the head, L(Z), along the X-axis from the back plane, L(Y), and along the Y-axis from the anterior superior spine of the ilium, L(X). However, since body symmetry with respect to the sagittal plane was assumed, L(Y) was defined as equal to one-half the bispinous breadth (Appendix III).

Figure 3. Reference Landmarks for Location of Center of Gravity

SELECTION OF BODY POSITIONS

Eight body positions (figure 4) were defined. Factors which were considered in the selection of the positions included the desirability of a standard anthropometric posture (Standing), the capability of determining the effect of changes in limb position on moment of inertia, (Standing, Arms Over Head; Sitting, Forearms Down) positions predicted to yield maximum and minimum moment of inertia values (Spread Eagle; Sitting, Thighs Elevated), and special applications (Mercury Configuration, Relaxed-Weightless).

DESCRIPTION OF POSITIONS

- | | |
|-----------------------------|--|
| 1. STANDING | Subject stands erect with head oriented in the Frankfort plane and with arms hanging naturally at the sides as described in WADC TR 52-321 stature measurement (reference 7). |
| 2. STANDING, ARMS OVER HEAD | Legs, torso and head same as position 1; upper extremities raised over head, parallel to Z-axis; wrist axes parallel to X-axis; hands slightly clenched. |
| 3. SPREAD EAGLE | Torso and head same as position 1; subject against plane parallel to YZ plane; arms at 45° with Z-axis, legs at 30° with Z-axis; wrist axes parallel to YZ plane; hands slightly clenched. |
| 4. SITTING | Upper legs and forearms parallel to X-axis; upper arms, lower legs and spine parallel to Z-axis; soles parallel to XY plane; wrist axes parallel to Z-axis; head in Frankfort plane. |
| 5. SITTING, FOREARMS DOWN | Same as position 4, except forearms parallel to Z-axis, wrist axes parallel to X-axis. |
| 6. SITTING, THIGHS ELEVATED | Same as position 4, except upper leg angle approximately 35° with YZ plane. |
| 7. MERCURY CONFIGURATION | Same as position 4, except 100° back-thigh angle, thigh-leg angle 112°, forearm parallel to thigh. |
| 8. RELAXED (WEIGHTLESS) | Position predicted to be assumed by a human, relaxed in the weightless state.*
See figure 4. |

Figure 4. Body Positions

SECTION II

DESCRIPTION OF APPARATUS

DESIGN AND FABRICATION OF PENDULUMS

Two compound pendulums were designed in accordance with the criteria presented in reference 4 to accommodate the subject sample for the eight positions previously defined. One pendulum (I_{ox}/I_{oy}) was utilized for the determination of moment of inertia about the X and Y axes; the other was used for measurement about the Z-axis (I_{oz}). The pendulums, weighing in the range of 40 to 60 lbs., were constructed mainly of welded 1-inch aluminum tubing. The cone fulcrums, designed for minimum friction and wear, were fabricated of steel and tipped with hard-facing alloy; the cones rested on hardened steel pads. The pads were secured to a heavy steel support fixture which was anchored solidly to concrete. A hoist mechanism was devised to transfer the pendulums from the short to the long suspension axis and to rotate the I_{ox}/I_{oy} pendulum. The pendulums, suspended from the support fixture, are shown in figures 5 and 6.

INSTRUMENTATION

Since determination of moment of inertia by the use of a compound pendulum is dependent upon accurate measurement of the pendulum period, an electronic timer system was designed to measure time to within ± 0.0001 sec. The timer system consisted of a light source, a photo diode, an electronic counter (Hewlett Packard Model 522B), and reset and inhibition circuitry which permitted the measurement of either a single cycle or a series of cycles up to 10. A thin blackened rod, attached to each pendulum equidistant from the short suspension axes, interrupted the light source during oscillation to automatically start and stop the counter. The switch (rod, light source, and photo diode) can be seen in position in figure 5.

BODY RESTRAINT

Pressure-sensitive tape and Velcro tape (1- and 2-inch widths) were used to restrain the subjects in their proper positions and to ensure rigidity with respect to the pendulum. Shim material of low-density rigid polystyrene foam was utilized in various thicknesses and shapes to align and restrain the head, feet, knees and wrists of the subjects where necessary. The restraint materials and techniques were chosen to minimize artifacts in the measurement of human moment of inertia.

Figure 5. Moment-of-Inertia Measurement Apparatus (I_{oz} Pendulum)

Figure 6. Moment-of-Inertia Measurement Apparatus (I_{ox}/I_{oy} Pendulum)

SECTION III

EXPERIMENTAL PROCEDURE

SELECTION OF SUBJECTS

The sample of 66 male subjects was selected on the basis of stature and weight from North American Aviation employees to represent the Air Force population stature and weight characteristics described in reference 7. For this total sample whose stature-weight scattergram is shown in figure 7, 60 subjects are contained within the bounds of 1st and 99th percentile values of stature and weight and 50 within the area bounded by the 5th and 95th percentile values. The stature-weight correlation coefficient value for the total sample is approximately 0.6, in comparison with the Air Force population value of approximately 0.5 reported in reference 6.

Figure 7. Scattergram of Statures and Weights of 66 Subjects

ANTHROPOMETRY OF SUBJECTS

Fifty measurements were taken on each subject. These measurements, listed in table I, included thirty-five standard Air Force dimensions contained in reference 7, and fifteen other dimensions. The former are useful for describing the characteristics of the subject sample in relation to the Air Force population, while the latter are expected to be useful in determining other biophysical characteristics such as the weight of certain segments of the body, etc.

TABLE I
MEASUREMENT OF SUBJECTS

Age	Hip Breadth, Sitting
Ankle Circumference	Iliac Spine Height
Axillary Arm Circumference	Juxtanipple Skinfold
Biacromial Diameter	Knee Circumference, Standing
Biceps Circumference (Extended)	Lower Arm Length
Bispinous Breadth	Lower Thigh Circumference
Buttock-popliteal Length	Midaxillary Line, Xyphoid Skinfold
Buttock Circumference	Shoulder Height (Acromial Height)
Buttock Depth	Sitting Height
Calf Circumference	Span
Cervicale Height	Sphygmon Height
Chest Breadth	Stature
Chest Circumference	Substernale Height
Chest Depth	Suprasternale Height
Elbow Circumference (Extended)	Thigh Circumference
Fist Circumference	Tibiale Height
Foot Breadth	Triceps Skinfold
Foot Length	Trochanteric Height
Forearm Circumference (Extended)	Upper Arm Length
Hand Breadth at Metacarpale	Waist Breadth
Hand Length	Waist Circumference
Head Breadth	Waist Depth
Head Circumference	Waist Height
Head Length	Weight
Hip Breadth	Wrist Circumference

All measurements were made with standard anthropometric instruments in accordance with techniques specified in references 7 and 9. Lange skin-fold calipers* were used in obtaining skinfold thickness measurements. A description of the anthropometric dimensions is given in Appendix III.

* Cambridge Scientific Industries, 18 Poplar Street, Cambridge, Maryland.

CALIBRATION OF APPARATUS

Calibration of the apparatus, consisting of the timer and pendulums, was a straightforward procedure. The timer was checked with respect to accuracy by adjusting the period of the oscillator in the Hewlett Packard electronic counter to correspond with that of a secondary frequency standard maintained by the NAA Metrology Laboratory. This calibration insured a basic counter accuracy of 2 parts in 10^6 . The design of the photo-diode switch provided a pulse rise time at the input to the counter of approximately 1 microsec.

Reproducibility of period measurements was evaluated with the aid of an eight-foot simple pendulum oscillating through a one degree arc. It was found to be approximately ± 0.0001 sec. for single-cycle comparisons and approximately ± 0.00005 sec. for 10-cycle averages.

Moments of inertia and centers of gravity of the pendulums with respect to their short suspension axes were measured by taking at least 10 10-cycle averages of the periods for each suspension, axis and position. Fulcrum friction was reduced to a minimum by substituting lubricated glass plates for the steel pads. Fulcrum separations (ΔL) were measured with a height gage to about ± 0.001 inch. The pendulums were weighed to an accuracy of ± 0.01 lb. on a calibrated Triner scale.

The accuracy of the I_0 measurement was evaluated experimentally through the use of a 139-lb. machined steel block, approximately $2 \times 12 \times 20$ inches, having a computed I_0 about one axis of approximately 16.33 lb. in. sec.². Measured I_0 differed from the computed value by less than 1 percent.

Following calibration of the pendulums for positions 1, 2 and 3, a short pilot study was run to assess subject period reproducibility and to develop an effective restraint technique. The results of this study demonstrated that a period reproducibility of ± 0.0005 sec. could be maintained with all subjects capable of participating in the experiment even through fulcrum and axis transfers.

A restraint procedure finally evolved which utilized a combination of drafting tape, Velcro tape and polystyrene foam shim blocks. Head movement in the upright positions was found to be particularly critical and careful attention was required in its positioning and restraint.

MOMENT OF INERTIA AND CG DETERMINATION

The subject was instructed to be as relaxed as possible and to breathe normally during measurement.

Subject weight, both pre and post-run, was recorded for each position. The subject was weighed on a Fairbanks, Morse and Co. scale (Code 10737, accuracy ± 0.05 lb.) and measured while clad only in trunks or shorts whose weight ranged between 4 and 8 oz. The garment weight was assumed a part of the subject body weight in all cases.

After the subject assumed position on the pendulum, a check was made to ensure that the cg of the subject was within prescribed limits by noting the position of the pendulum axis with respect to a gravity reference line and shimming the subject where required. The subject was securely restrained to the pendulum in the proper position by use of masking and Velcro tape at appropriate locations on the body. (The restraint technique is demonstrated for both pendulums and all positions in figures 8 through 11.)

The pendulum was made to oscillate through an angle of $\pm 1^\circ$. At least two 10-cycle-period averages were taken for each suspension axis to ensure that reproducibility was achieved. The criterion for reproducibility was that successive average periods be within ± 0.0005 sec.

A body-reference distance from the top of the subjects' heads to the short-fulcrum suspension axis of the I_{ox}/I_{oy} pendulum was measured for each position, and air temperature was recorded.

SECTION IV

RESULTS

The experimental results of the study are summarized in tables II and III wherein the most significant statistical information is listed. Computer printout of all statistical data is contained in Appendix I. In Appendix II, the individual centers of gravity, moments of inertia and anthropometry for each subject are presented. Lists of symbols and definitions applicable to the computer program printout sheets can also be found in Appendices I and II.

All correlations presented in the tables are based upon subject weight averaged over all positions. This weight is recorded for each subject on his individual data sheet in Appendix II. Since weight variations were seldom greater than one pound, this procedure should not significantly affect correlation coefficients.

Table II presents the arithmetic means and standard deviations of the centers of gravity and moments of inertia of the sample along with the means and standard deviations of age, stature and weight. The mean centers of gravity for all body positions are shown graphically in figure 12. Body symmetry was assumed insofar as the Y-axis centers of gravity are concerned; hence, their means and standard deviations are independent of body position. This assumption was not involved in the determinations of the Y-axis moments of inertia, however.

Table III shows the results of the linear regression analysis of moment of inertia vs. stature and weight. The multiple correlation coefficients all exceed 0.9 with only three exceptions. These large values of R indicate a very strong dependence of moment of inertia on stature and weight, which combined with the relatively small values of standard error of estimate and the large sample size, demonstrate the usefulness of the regression equation as a predictive tool. Regression equations, with which I_o values can be computed from stature and weight, are given for each position and axis.

The general equations of motion of a body involve an inertial tensor whose elements consist of the parameters measured in this study, i.e., the moments of inertia I_x , I_y , I_z , and the products of inertia I_{xy} , I_{xz} , I_{yz} . Although the determination of the latter was beyond the scope of this experiment, it can be shown (reference 5) that the largest of these, I_{xz} , can be found using a modification of the compound pendulum method.

SECTION V

SUMMARY

A study was conducted to determine the moments of inertia and centers of gravity of a sample of 66 living male subjects representative of the Air Force population in stature and weight ($r = 0.6$, S.D. = 2.3). Eight positions were investigated: Standing; Standing, Arms Over Head; Spread Eagle; Sitting; Sitting, Forearms Down; Sitting, Thighs Elevated; Mercury Configuration; and Relaxed (Weightless). A set of 50 anthropometric dimensions was taken on each subject, as well as record photographs in each position. The experimental procedure was based upon the compound pendulum. Results of a brief statistical analysis indicate the following:

1. Moment of inertia correlates very well with subject stature and weight in all positions and axes. Multiple linear correlation coefficients ranged between 0.77 and 0.98. Since standard errors were small, the derived regression equations constitute a useful tool for the prediction of subject moment of inertia from stature and weight alone.
2. The moments of inertia for all positions ranged from 6 to 211 lb. in sec.², with means from 11 to 152 lb. in sec.². The data as a whole are consistent, changing in magnitude of I_c as body position shifts.
3. Centers of gravity data exhibit the same consistency; mean cg shifts relate as expected to changes in limb position.

The data contained in this report provide a basis for total-body dynamic analysis. Relative to the test sample or other similar populations, individual centers of gravity can now be estimated and moments of inertia computed from easily obtainable anthropometric dimensions.

APPENDIX I

STATISTICAL DATA

SYMBOLS USED IN PRINTOUT

A, B	Regression equation constants, stature vs. weight
A(X), A(Y),...C(Z)	Regression equation constants with respect to denoted axis for single and multiple moment-of-inertia correlations
AV	Arithmetic mean of the sample
AVL(X)	Arithmetic mean of the centers of gravity along the X-axis measured with respect to the back plane
AVL(Y)	Arithmetic mean of the centers of gravity along the Y-axis; equal to one-half the average bispinous distance
AVL(Z)	Arithmetic mean of the centers of gravity along the Z-axis measured with respect to the top of the head
AVI(X), AVI(Y), AVI(Z)	Arithmetic means of the moments of inertia with respect to the X, Y and Z axes respectively
R(X), R(Y), R(Z)	Correlation coefficients with respect to X, Y and Z axes for single and multiple moment-of-inertia correlations
RHWT	Correlation coefficient, stature vs. weight
S(X), S(Y), S(Z)	Standard errors of estimates with respect to the X, Y and Z axes for single and multiple moment-of-inertia correlations
SD	Standard deviations from the mean
SDL(X), SDL(Y), SDL(Z)	Standard deviations of the centers of gravity from AVL(X), AVL(Y) and AVL(Z) respectively
SDI(X), SDI(Y), SDI(Z)	Standard deviations of the moments of inertia from AVI(X), AVI(Y) and AVI(Z) respectively
SHWT	Standard error of estimate, stature vs. weight
STAT	Stature
WT	Subject weight

APPENDIX II

SUBJECT DATA

The computed moments of inertia and centers of gravity for the individual subjects together with the corresponding anthropometric dimensions are presented in the following pages. The data are for the most part self-explanatory. Definitions of the symbols and abbreviations are reproduced here for the convenience of the reader. Floating point numbers are read conventionally, e.g., 274+02 means 0.274×10^2 .

- L(X) Distance to the center of gravity of the subject as measured along the X-axis from the back plane.
- L(Y) Distance to the center of gravity of the subject measured along the Y-axis from the iliac crest. Since body symmetry with respect to the sagittal plane is assumed, L(Y) is equal to one-half the bispinous breadth.
- L(Z) Distance to the subject center of gravity measured along the Z-axis from the top of the head.
- I(X) Moment of inertia about the X-axis through the subject's center of gravity.
- I(Y) Moment of inertia about the Y-axis through the subject's center of gravity.
- I(Z) Moment of inertia about the Z-axis through the subject's center of gravity.

ABBREVIATIONS OF ANTHROPOMETRIC DIMENSIONS

Ankle C	Ankle Circumference
Axillarm C	Axillary Arm Circumference
Biacrom D	Biacromial Diameter
Bicep C	Biceps Circumference (Extended)
Bispin B	Bispinous Breadth
Butpop L	Buttock-popliteal Length
Butt C	Buttock Circumference
Butt D	Buttock Depth
Calf C	Calf Circumference
Cervic H	Cervicale Height
Chest B	Chest Breadth
Chest C	Chest Circumference
Chest D	Chest Depth
Elbow C	Elbow Circumference (Extended)
Fist C	Fist Circumference
Foot B	Foot Breadth
Foot L	Foot Length
Forearm C	Forearm Circumference (Extended)
Hand B	Hand Breadth at Metacarpale
Hand L	Hand Length
Head B	Head Breadth
Head C	Head Circumference
Head L	Head Length
Hip B	Hip Breadth
Hip B Sit	Hip Breadth, Sitting
Iliac H	Iliac Spine Height
Juxta S	Juxtanipple Skinfold
Knee C	Knee Circumference, Standing
Lowarm L	Lower Arm Length
Lowthigh C	Lower Thigh Circumference
Malx S	Midaxillary Line, Xyphoid Skinfold
Shldr H	Shoulder Height (Acromial Height)
Sit H	Sitting Height
Span	Span

(WEIGHT IN LBS, LENGTH IN INCHES, MOMENT OF INERTIA IN LB-IN-(SEC)SQ)

APPENDIX III
DESCRIPTION OF ANTHROPOMETRIC DIMENSIONS

1. ANKLE CIRCUMFERENCE: Subject stands. Holding the tape slightly above the projections of the ankle bones, measure the minimum circumference of the right ankle (reference 7).
2. AXILLARY ARM CIRCUMFERENCE: Subject stands, right arm initially raised and then lowered after the tape is in place. Holding the tape in a horizontal plane and as high as possible in the armpit, measure the circumference of the upper arm (reference 7).
3. BIACROMIAL DIAMETER: Subject sits erect, upper arms hanging at sides and forearms extended horizontally. Using the anthropometer, measure between points marked at the ends of the shoulders (acromion to acromion) (reference 7, Appendix IV).
4. BICEPS CIRCUMFERENCE (Extended): Subject stands with right arm extended at side. Holding the tape in a horizontal plane, measure the maximum circumference of the biceps muscle.
5. BISPINOUS BREADTH: Subject stands erect. Using the anthropometer measure the distance between the anterior superior spines of the ilium (most anterior bony projections of the hip bone) previously marked (Appendix IV).
6. BUTTOCK-POPLITEAL LENGTH: Subject sits with knees bent at right angles. Measure the maximum horizontal distance from the point of intersection of the right angle behind the right knee (popliteal area) to the buttocks.
7. BUTTOCK CIRCUMFERENCE: Subject stands erect. Holding the tape in a horizontal plane, measure the circumference of the buttocks at the level of the greatest rearward protrusion (reference 7).
8. BUTTOCK DEPTH: Subject stands erect. Holding the anthropometer horizontally at the subject's right side, measure the depth of the buttocks at the level of the greatest rearward protrusion (reference 7).
9. CALF CIRCUMFERENCE: Subject stands. Holding the tape in a horizontal plane, measure the maximum circumference of the right calf (reference 7).
10. CERVICALE HEIGHT: Subject stands erect. Using the anthropometer, measure the vertical distance from the floor to the point marked on the bony projection (the 7th cervical vertebra) at the posterior base of the neck (reference 7).

11. CHEST BREADTH Subject stands erect with arms initially raised and then lowered after the anthropometer is placed. Measure the chest breadth at the level of the nipples, during normal breathing (reference 7).
12. CHEST CIRCUMFERENCE Subject stands erect with arms initially raised and then lowered after the tape is in place. Holding the tape in a horizontal plane at the level of the nipples, measure the maximum circumference of the chest during normal breathing (reference 7).
13. CHEST DEPTH Subject stands erect with arms initially raised and then lowered after the instrument is in place. Holding the anthropometer horizontally on the subject's right side, at the level of the nipples, measure the chest depth during normal breathing (reference 7).
14. ELBOW CIRCUMFERENCE (Extended) Subject stands with right arm extended. Measure the elbow circumference holding the tape over the olecranon.
15. FIST CIRCUMFERENCE Subject makes a tight fist with right hand, thumb lying across the end of the fist. Measure the fist circumference with tape passing over the thumb and the knuckles (reference 7).
16. FOOT BREADTH Subject stands with right foot in the foot box, weight equally distributed, the foot just touching the side and rear walls, and long axis of the foot parallel to the side wall. Using the scale on the base of the foot box, measure the widest breadth of the foot (reference 7).
17. FOOT LENGTH Subject stands with right foot in the foot box, weight equally distributed, foot just touching the side and rear walls, and long axis of the foot parallel to the side wall. Using the scale on the base of the foot box, measure the length of the foot along the long axis (reference 7).
18. FOREARM CIRCUMFERENCE (Extended) Subject stands, right arm extended. Measure the maximum circumference of the forearm with tape.
19. HAND BREADTH AT METACARPALE Subject extends right hand. With the bar of sliding caliper across the palm, measure the maximum breadth across the distal ends of the metacarpal bones (knuckles) (reference 7).
20. HAND LENGTH Subject extends right hand. With the bar of the sliding caliper lying across the palm, measure the hand length from the proximal edge of the navicular bone at the wrist to the tip of the middle finger (reference 7).
21. HEAD BREADTH Using spreading calipers, measure the maximum breadth of the head in a plane perpendicular to the mid-sagittal plane (reference 7).

22. HEAD CIRCUMFERENCE: With tape passing above (not including) the brow ridges, measure the maximum circumference of the head (reference 7).
23. HEAD LENGTH: Using spreading calipers, measure the maximum length of the head from glabella to the occipital region (reference 7).
24. HIP BREADTH: Subject stands erect. Holding the anthropometer horizontally, measure the maximum breadth of the hips (reference 7).
25. HIP BREADTH, SITTING: Subject sits erect. Holding the anthropometer horizontally, measure the maximum breadth of the hips (reference 7).
26. ILIAC SPINE HEIGHT: Subject stands erect. Using the anthropometer measure the vertical distance from the floor to the mark of the anterior superior spine of the ilium on the right side (Appendix IV).
27. JUXTANIPPLE SKINFOLD: Subject stands erect. Using skinfold calipers measure the skinfold thickness just adjacent to the right nipple, along the line between the anterior crease of the axilla and the nipple. Grasp skinfold between thumb and index finger, enough to include two thicknesses of skin and subcutaneous fat but not muscle or fascia. Apply calipers 1 cm from fingers holding skinfold, and at a depth from the edge of the skinfold equal to the thickness of the fold. Skinfold thickness is taken in the vertical plane except when lines of Linn result in torsion of the skinfold, and then the skinfold is taken along these lines (reference 9).
28. KNEE CIRCUMFERENCE, STANDING: Subject stands. Measure the right knee circumference at the mid-patella level holding the tape in a horizontal plane.
29. LOWER ARM LENGTH: Subject stands with right arm extended at side. Using an anthropometer measure the distance along the long axis of the lower arm between points marked at radiale and stylium (Appendix IV).
30. LOWER THIGH CIRCUMFERENCE: Subject stands. Holding the tape in a horizontal plane measure the circumference of the lower thigh just above the right knee (reference 7).
31. MIDAXILLARY LINE, XYPHOID SKINFOLD: Subject stands erect. Using skinfold calipers measure the skinfold thickness in the mid-axillary line at the level of the xiphoid on the right side of the body. Grasp skinfold between thumb and index finger, enough to include two thicknesses of skin and subcutaneous fat but not muscle or fascia. Apply calipers 1 cm from fingers holding skinfold, and at a depth from the edge of the skinfold equal to the thickness of the fold. Skinfold thickness is taken in the vertical plane except when lines of Linn result in torsion of the skinfold, and then the skinfold is taken along these lines (reference 9).

32. SHOULDER HEIGHT (Acromial Height): Subject stands erect. Using the anthropometer, measure the vertical distance from the floor to the right acromion, previously marked (reference 7).
33. SITTING HEIGHT: Subject sits erect, head oriented in the Frankfort plane and feet resting on a surface so that knees are bent at about right angles. Using the anthropometer, measure the vertical distance from the sitting surface to the top of the head by placing the anthropometer firmly against the scalp (reference 7).
34. SPAN: Subject stands erect against a previously-calibrated rear wall with arms extended laterally at their maximum. With one hand touching a surface perpendicular to the rear wall, measure the maximum span by placing a block against the finger tips of the other hand (reference 7).
35. SPHYRION HEIGHT: Subject stands with legs slightly apart. Using measuring block measure the vertical distance from floor to sphyrion previously marked (Appendix IV).
36. STATURE: Subject stands erect with head oriented in the Frankfort plane. Using the anthropometer measure the vertical distance from the floor to the top of the head by placing the anthropometer firmly against the scalp (reference 7).
37. SUBSTERNAL HEIGHT: Subject stands erect. Using the anthropometer measure the vertical distance from the floor to a marked point at the lower edge of the breastbone (substernale) (reference 7, Appendix IV).
38. SUPRASTERNAL HEIGHT: Subject stands erect. Using the anthropometer, measure the vertical distance from the floor to the marked point at the upper edge of the breastbone (suprasternale)(reference 7, Appendix IV).
39. THIGH CIRCUMFERENCE: Subject stands with legs slightly apart. Holding the tape in a horizontal plane just below the lowest point in the gluteal furrow. Measure the circumference of the right thigh (reference 7).
40. TIBIALE HEIGHT: Subject stands with legs slightly apart. Using the anthropometer measure the vertical distance from floor to right tibiale previously located and marked (Appendix IV).
41. TRICEPS SKINFOLD: Subject stands with right upper arm extended forward and elbow in 90° flexion. Mark the posterior midpoint between the tip of the acromion and olecranon. Grasp skinfold between thumb and index fingers, enough to include two thickness of skin and subcutaneous fat but not muscle or fascia. Allowing the right arm to extend straight at the side, apply calipers 1 cm from fingers holding skinfold, and at a depth from the edge of the skinfold equal to the thickness of the fold. Skinfold thickness is taken in the vertical plane except when lines of Linn result in torsion of the skinfold and then the skinfold is taken along these lines (reference 9).

42. TROCHANTERIC HEIGHT: Subject stands erect. Using the anthropometer measure the vertical distance from the floor to trochanterion previously marked on the right side (Appendix IV).
43. UPPER ARM LENGTH: Subject stands with right arm extended at side. Using an anthropometer measure the distance along the long axis of the upper arm, between the points previously marked at acromion and at radiale (Appendix IV).
44. WAIST BREADTH: Subject stands erect with abdomen relaxed. Using the anthropometer, measure the minimum horizontal distance between the points marking the most lateral indentation in the abdominal region (reference 7).
45. WAIST CIRCUMFERENCE: Subject stands erect with abdomen relaxed. Using the tape, measure the minimum circumference around the abdominal region, passing over the most lateral indentation waist points (reference 7).
46. WAIST DEPTH: Subject stands erect with abdomen relaxed. Holding the anthropometer horizontally on the subject's right side, measure the anterior to posterior distance of the abdomen at the level of the most lateral indentation waist points (reference 7).
47. WAIST HEIGHT: Subject stands erect. Using the anthropometer, measure the vertical distance from the floor to the most lateral indentation point in the abdominal region on the right side (reference 7).
48. WRIST CIRCUMFERENCE: Right arm and hand extended. Passing the tape just proximal of the styloid process of the ulna, measure the minimum circumference of the wrist (reference 7).

APPENDIX IV
SKELETAL ANTHROPOMETRIC POINTS

SKELETAL ANTHROPOMETRIC POINTS

Aerospace Medical Division 6570th Aerospace Medical Research Laboratories, Wright-Patterson AFB, Ohio Rpt. No. AFRL-TDR-63-36. MOMENTS OF INERTIA AND CENTERS OF GRAVITY OF THE LIVING HUMAN BODY. A study was conducted to determine the moments of inertia and centers of gravity of a sample of 66 living male subjects representative of the Air Force population in stature and weight. Eight body positions were investigated: Standing; Standing, Arms Over Head; Spread Eagle; Sitting; Sitting, Forearms Down;	II. Contract AF 33(657)-7848 II. North American Aviation, Inc., Los Angeles, Calif. sitting, Thighs Elevated; Mercury Configuration; Relaxed (Weightless). The procedure was based upon the compound pendulum having a theoretical accuracy of approximately $\pm 2\%$ to ± 8 per cent depending upon position and axis. Orthogonal axes, defined as the intersections of the sagittal, frontal, and transverse planes through the standing body, were designated as X, Y, and Z. A set of 50 anthropometric dimensions was taken on each subject, as well as photographs of each subject in each position.	IV. Santschi, W. R. Dubois, J. Omoto, C. V. In DDC collection VI. Results of the study show that the average moment of inertia varied in this sample from 11 lb. in sec. 2, about the Z axis to 152 lb. in sec. 2, about the X axis. Linear regression analysis of moments of inertia vs. stature and weight yielded correlation coefficients ranging between 0.77 and 0.98		Results of the study show that the average moment of inertia varied in this sample from 11 lb. in sec. 2, about the Z axis to 152 lb. in sec. 2, about the X axis.
